

Student Answer Sheet

Subject: Artificial Intelligence

Definition:

AI refers to computer programmes that can think and act like humans. These systems can process information, draw conclusions from data, and correct themselves over time. They handle jobs that normally need a human brain, such as understanding spoken words or identifying objects in pictures.

Body:

Under the AI umbrella, statistical learning systems (often called ML) train on examples to make predictions. Layered computational graphs (deep networks) are especially good at recognising images and speech. Text-processing pipelines help computers read and write human language. Intelligent robots use vision and planning to operate in the physical world. Doctors use AI to spot diseases in scans; banks use it to catch suspicious transactions; car makers use it to build vehicles that steer themselves.

Conclusion:

Intelligent systems are reshaping how work gets done across every sector. The gains in speed and accuracy are remarkable, but questions of fairness, accountability, and worker impact cannot be ignored. Building AI that is explainable and aligned with human values will be the central challenge of the coming decades.
