

# Student Answer Sheet

Subject: Artificial Intelligence

## Definition:

The water cycle describes how water evaporates from the surface of the Earth, rises into the atmosphere, cools and condenses into clouds, and falls back to the surface as precipitation. This cycle is essential for life on Earth.

## Body:

The main stages of the water cycle are evaporation, condensation, precipitation, and collection. Evaporation occurs when liquid water is heated by the sun and turns into water vapour. This vapour rises into the atmosphere and cools to form clouds through condensation. Precipitation falls as rain or snow and is collected in rivers, lakes, and oceans, restarting the cycle.

## Conclusion:

The water cycle is fundamental to all ecosystems on Earth. It regulates temperature, distributes fresh water, and supports plant and animal life. Human activities like deforestation and pollution can disrupt the water cycle.
